

Modules and Packages

CS195 - Lecture 12

Instructor: Dr. V

Lecture 12

- `import`, `from`, `as`
- importing from your other `.py` files
- `dir()`
- docstrings
- `if __name__ == "__main__":`
- `sys.argv`
- directories as packages and subpackages
 - `__init__.py`
 - `__all__`
 - intra-package references (`..`, `...`, `.....`, etc)
- `sys.path`

import, from, as

import modules

```
1 # import random and time modules
2 import random
3 import time
4
5 # sleep for 1sec
6 time.sleep(1)
7 # print random integer between 0 and 9
8 print( random.randrange(10) )
```

9

10

11

12

13

14

15

import modules

```
1 # import random and time modules
2 import random, time
3
4
5 # sleep for 1sec
6 time.sleep(1)
7 # print random integer between 0 and 9
8 print( random.randrange(10) )
```

9

10

11

12

13

14

15

import specific functions from modules

```
1 # import randrange, randint, sleep from random and time modules
2 from random import randrange, randint
3 from time import sleep
4
5 # sleep for 1sec
6 sleep(1)
7 # print random integer between 0 and 9
8 print( randrange(10) )
9 # print random integer between 1 and 10
10 print( randint(1,10) )
11
12
13
14
15
```

import specific functions from modules

```
1 # import everything from random, and one method (sleep) from time
2 from random import *
3 from time import sleep
4
5 # sleep for 1sec
6 sleep(1)
7 # print random integer between 0 and 9
8 print( randrange(10) )
9 # print random integer between 1 and 10
10 print( randint(1,10) )
11
12
13
14
15
```

using **as** to rename functions

```
1 # import random.choice and rename it to randchoice
2 from random import choice as randchoice
3
4 GREETINGS = ['hello', 'good afternoon', 'yo', 'what up', 'sup']
5
6 # print random greeting
7 print( randchoice(GREETINGS) )
```

using **as** to rename modules

```
1 # import random module and rename it to rand
2 import random as rand
3
4 GREETINGS = ['hello', 'good afternoon', 'yo', 'what up', 'sup']
5
6 # print random greeting
7 print( rand.choice(GREETINGS) )
8
9
10
11
12
13
14
15
```

your .py files are
modules too

importing from your other .py files

```
1 #fileA.py
2 import random as rand
3
4 GREETING = 'hello'
5
6 def foo() -> int:
7     '''Returns a random integer
8     between 1 and 100.'''
9     return rand.randint(1,100)
10
11
12 def bar(x:int,y:int)->int:
13     '''Returns a random integer
14     between x and y.'''
15     return rand.randint(x,y)
```

```
1 #fileB.py
2 import fileA
3
4 print( fileA.GREETING )
5
6 print( fileA.foo() )
7
8 print( fileA.bar(1,10) )
9
10
11
12
13
14
15
```

importing from your other .py files

```
1 #fileA.py
2 import random as rand
3
4 GREETING = 'hello'
5
6 def foo() -> int:
7     '''Returns a random integer
8     between 1 and 100.'''
9     return rand.randint(1,100)
10
11
12 def bar(x:int,y:int)->int:
13     '''Returns a random integer
14     between x and y.'''
15     return rand.randint(x,y)
```

```
1 #fileB.py
2 from fileA import foo,bar
3
4 print( foo() )
5
6 print( bar(1,10) )
7
8
9
10
11
12
13
14
15
```

importing from your other .py files

```
1 #fileA.py
2 import random as rand
3
4 GREETING = 'hello'
5
6 def foo() -> int:
7     '''Returns a random integer
8     between 1 and 100.'''
9     return rand.randint(1,100)
10
11
12 def bar(x:int,y:int)->int:
13     '''Returns a random integer
14     between x and y.'''
15     return rand.randint(x,y)
```

```
1 #fileB.py
2 from fileA import *
3
4 print( GREETING )
5
6 print( foo() )
7
8 print( bar(1,10) )
9
10
11
12
13
14
15
```

importing from your other .py files

```
1 # "file A.py" <- spaces in name
2 import random as rand
3
4 def foo() -> int:
5     '''Returns a random integer
6     between 1 and 100.'''
7     return rand.randint(1,100)
8
9
10 def bar(x:int,y:int)->int:
11     '''Returns a random integer
12     between x and y.'''
13     return rand.randint(x,y)
14
15
```

```
1 #fileB.py
2 fileA = __import__('file A')
3
4 print( fileA.foo() )
5
6 print( fileA.bar(1,10) )
7
8
```

- it's better to name your python files using the same syntax as variable names
- if this is not possible, the workaround is to use `__import__('file name')`

15

dir()

```
1 #fileA.py
2 import random as rand
3
4 GREETING = 'hello'
5
6 def foo() -> int:
7     '''Returns a random integer
8     between 1 and 100.'''
9     return rand.randint(1,100)
10
11
12 def bar(x:int,y:int)->int:
13     '''Returns a random integer
14     between x and y.'''
15     return rand.randint(x,y)
```

```
1 #fileB.py
2 import fileA
3
4 #dir(X) will list all
5 # members of X
6
7 #in the case of modules,
8 # dir(module) will list all
9 # vars, functions, classes,
10 # and imported modules
11 # in the module
12 print( dir(fileA) )
13
14
15
```

module docstrings, __doc__, __name__

```
1 #fileA.py
2 '''my stuff (version 1.1)
3
4 includes foo() and bar()...'''
5
6 import random as rand
7
8 def foo() -> int:
9     '''Get rand int 1 to 100'''
10     return rand.randint(1,100)
11
12
13 def bar(x:int,y:int)->int:
14     '''Get rand int x to y'''
15     return rand.randint(x,y)
```

```
1 #fileB.py
2 import fileA as mymod
3
4
5 # print fileA name
6 print( mymod.__file__ )
7
8 # print fileA name
9 print( mymod.__name__ )
10
11 # print fileA docstring
12 print( mymod.__doc__ )
13
14
15
```

main script vs module

- run `fileA.py` as main script
 - in terminal:
 - `python fileA.py`
- import from `fileA.py` as a module
 - in some `fileB.py`:
 - `import fileA`
 - `from fileA import ...`
- ...but what if you wanted to be able to run `fileA.py` in a different way depending on whether it was the main script or imported as a module?

`__name__ == '__main__'`

- use `if __name__ == '__main__':` to ensure that your `<<codeBlock>>` only runs if this python file runs as main script, but never when it's imported as a module
 - two underscores before and two after `name`
 - two underscores before and two after `main`

importing from your other .py files

```
1 #fileA.py
2 import random as rand
3
4 def foo() -> int:
5     '''Random int 1 to 100.'''
6     return rand.randint(1,100)
7
8
9 print('print this either way')
10
11 if __name__=='__main__':
12     print('hello from file A')
13     print( foo() )
14
15
```

```
1 #fileB.py
2 from fileA import *
3
4 print('hello from file B')
5 print( foo() )
6
7
```

- what is the output when we run the following in terminal:
 - python fileA.py
 - python fileB.py

importing from your other .py files

```
1 #fileA.py
2 import random as rand
3
4 def foo() -> int:
5     '''Random int 1 to 100.'''
6     return rand.randint(1,100)
7
8
9 print('print this either way')
10
11 if __name__=='__main__':
12     print('hello from file A')
13     print( foo() )
14
15
```

```
1 #fileB.py
2 from fileA import *
3
4 print('hello from file B')
5 print( foo() )
6
7
```

- python fileA.py:
 - print this either way
 - hello from file A...
- python fileB.py:
 - print this either way
 - hello from file B...

sys.argv

sys.argv

- python scripts can accept arguments from terminal:
 - `python fileA.py arg1 arg2 arg3...`
 - if you import the `sys` module, you'll be able to access `arg1`, `arg2`, `arg3` as `sys.argv[1]`, `sys.argv[2]`, and `sys.argv[3]`, respectively
- `sys.argv` is a list of strings
- add this to `hello.py`:

```
import sys
print(sys.argv)
```
- then run in terminal: `python hello.py 11 12 abc`

sys.argv

```
1 # hello.py
2 import sys
3
4 if __name__ == '__main__':
5     if len(sys.argv) > 1:
6         print(f'hello {sys.argv[1]}!')
7     else:
8         print('hello!')
9
10 # what would this code output if in terminal you ran:
11 # > python hello.py
12
13 # what if you ran:
14 # > python hello.py joejoe
15
```

directories as
packages

python packages

- if you want two or more modules to be in the same package, add them to a folder; e.g.,
 - add **mod1.py** and **mod2.py** to folder called **pkg**
 - how you can do things like this:
 - import both mod1 and mod2
 - from pkg import mod1, mod2
 - import everything from mod1
 - from pkg.mod1 import *
 - import mod2 module
 - from pkg import mod2
 - import pkg.mod2 as mod2
 - import pkg.mod2

pkg

mod1.py

mod2.py

importing modules from packages

```
1 # pkg/mod2.py
2 '''module 2'''
3
4 import random as rand
5
6
7 GREETING = 'hello'
8
9 x = 10
10
11 def foo() -> int:
12     '''Get rand int 1 to 100'''
13     return rand.randint(1,100)
14
15
```

```
1 # hello.py
2
3
4 import pkg.mod2
5
6
7 print( pkg.mod2.GREETING )
8 print( pkg.mod2.x )
9 print( pkg.mod2.foo() )
10
11
12
13
14
15
```

importing modules from packages

```
1 # pkg/mod2.py
2 '''module 2'''
3
4 import random as rand
5
6
7 GREETING = 'hello'
8
9 x = 10
10
11 def foo() -> int:
12     '''Get rand int 1 to 100'''
13     return rand.randint(1,100)
14
15
```

```
1 # hello.py
2
3
4 import pkg.mod2 as mod2
5
6
7 print( mod2.GREETING )
8 print( mod2.x )
9 print( mod2.foo() )
10
11
12
13
14
15
```

importing modules from packages

```
1 # pkg/mod2.py
2 '''module 2'''
3
4 import random as rand
5
6
7 GREETING = 'hello'
8
9 x = 10
10
11 def foo() -> int:
12     '''Get rand int 1 to 100'''
13     return rand.randint(1,100)
14
15
```

```
1 # hello.py
2
3
4 from pkg import mod2
5
6
7 print( mod2.GREETING )
8 print( mod2.x )
9 print( mod2.foo() )
10
11
12
13
14
15
```

importing from modules in packages

```
1 # pkg/mod2.py
2 '''module 2'''
3
4 import random as rand
5
6
7 GREETING = 'hello'
8
9 x = 10
10
11 def foo() -> int:
12     '''Get rand int 1 to 100'''
13     return rand.randint(1,100)
14
15
```

```
1 # hello.py
2
3
4 from pkg.mod2 import *
5
6
7 print( GREETING )
8 print( x )
9 print( foo() )
10
11
12
13
14
15
```

importing modules vs packages

- in general, you can only import modules, not packages; e.g.,
 - `import pkg.mod1` # imports `mod1.py` module from `pkg`
- however, your package folder should have a file called `__init__.py`, which is a namesake module for the package, and you can import it (and from it)
 - `import pkg` # import `__init__.py` module from `pkg`
- **WARNING:** `__init__.py` file will run regardless of which modules are imported from the package

importing from packages

```
1 # pkg/__init__.py
2 '''pkg (v1.0)'''
3
4
5
6 print('loading __init__.py...')
7
8 a,b = 1,2
9
10 def foobar():
11     print(a+b)
12
13
14
15
```

```
1 # hello.py
2
3
4 import pkg
5
6 pkg.foobar()
7
8 print( pkg.mod2.GREETING )
9
10
11
12
13
14
15
```

- what is the output when we run the following in terminal:
 - python hello.py

importing from packages

```
1 # pkg/__init__.py
2 '''pkg (v1.0)'''
3
4
5
6 print('loading __init__.py...')
7
8 a,b = 1,2
9
10 def foobar():
11     print(a+b)
12
13
14
15
```

```
1 # hello.py
2
3
4 import pkg
5 # this will print:
6     loading __init__.py...
7
8 pkg.foobar()
9 # this will print:
10     3
11
12 print( pkg.mod2.GREETING )
13 # this will throw an error
14 #     because there's no mod2
15 #     in __init__.py
```

importing from packages

```
1 # pkg/__init__.py
2 '''pkg (v1.0)'''
3
4
5
6 print('loading __init__.py...')
7
8 a,b = 1,2
9
10 def foobar():
11     print(a+b)
12
13
14
15
```

```
1 # hello.py
2
3
4 import pkg, pkg.mod2
5
6 pkg.foobar()
7
8 print( pkg.mod2.GREETING )
9
10
11
12
13
14
15
```

- what is the output when we run the following in terminal:
 - python hello.py

packages and subpackages

sound/

__init__.py

formats/

__init__.py

wav.py

mp3.py

...

effects/

__init__.py

echo.py

surround.py

...

filters/

__init__.py

equalizer.py

karaoke.py

...

Top-level package

Initialize the sound package

Subpackage for file format conversions

Subpackage for sound effects

Subpackage for filters

Let's say you want to build a package for processing sound...

packages and subpackages

```
1 # main.py
2 # what is the expected output?
3
4 from sound.formats import mp3
5
6 print( mp3.FILE_EXTENSION )
7
```

```
1 # sound/__init__.py
2
3 print('initiating \
4     sound/__init__.py''')
5
6
7
```

```
1 # sound/formats/__init__.py
2
3 print('initiating \
4     sound/formats/__init__.py''')
5
6
7
```

```
1 # sound/formats/mp3.py
2
3 FILE_EXTENSION = '.mp3'
4
5 print('hello from mp3.py')
6
7
```

packages and subpackages

```
1 # main.py
2
3 # what if you wanted to import
4 # all the formats?
5 from sound.formats import *
6
7
```

```
1 # sound/formats/__init__.py
2
3 # you would expects all format
4 # modules to be listed here
5
6
7
```

```
1 # sound/formats/wav.py
2
3 FILE_EXTENSION = '.wav'
4
5 print('hello from wav.py')
6
7
```

```
1 # sound/formats/mp3.py
2
3 FILE_EXTENSION = '.mp3'
4
5 print('hello from mp3.py')
6
7
```

packages and subpackages

```
1 # main.py
2
3 # what if you wanted to import
4 # all the formats?
5 from sound.formats import *
6
7
```

```
1 # sound/formats/__init__.py
2
3 # this would import all modules
4 # from package, but you
5 # SHOULD NOT do this. why?
6 from . import wav,mp3,aiff,au
7
```

```
1 # sound/formats/wav.py
2
3 FILE_EXTENSION = '.wav'
4
5 print('hello from wav.py')
6
7
```

```
1 # sound/formats/mp3.py
2
3 FILE_EXTENSION = '.mp3'
4
5 print('hello from mp3.py')
6
7
```

packages and subpackages

```
1 # main.py
2
3 # what if you wanted to import
4 # just one module from
5 # formats?
6 from sound.formats import mp3
7
```

```
1 # sound/formats/__init__.py
2
3 # all of these would have to
4 # get processed anyway!
5 from . import wav, mp3, aiff, au
6
7
```

```
1 # sound/formats/wav.py
2
3 FILE_EXTENSION = '.wav'
4
5 print('hello from wav.py')
6
7
```

```
1 # sound/formats/mp3.py
2
3 FILE_EXTENSION = '.mp3'
4
5 print('hello from mp3.py')
6
7
```

packages and subpackages

```
1 # main.py
2
3 # what if you wanted to import
4 # all the formats?
5 from sound.formats import *
6
7
```

```
1 # sound/formats/__init__.py
2
3 # do this to list all
4 # modules importable via *:
5 __all__ = ['wav', 'mp3', ...]
6
7
```

```
1 # sound/formats/wav.py
2
3 FILE_EXTENSION = '.wav'
4
5 print('hello from wav.py')
6
7
```

```
1 # sound/formats/mp3.py
2
3 FILE_EXTENSION = '.mp3'
4
5 print('hello from mp3.py')
6
7
```

Intra-package references

- if you want to reference what's inside the `wav.py` module from `mp3.py`, you can import `wav.py` from `mp3.py`:
 - `from sound.format import wav` # absolute reference
 - `from . import wav` # relative reference
 - the `.` indicates current package
 - `from ..format import wav` # relative reference
 - the double-dots (`..`) indicates parent package
 - add more double-dots to go higher in the hierarchy; e.g., four dots (`....`) indicates grandparent package

sys.path

- where does python search for packages and modules?
 - when your script says **import random** or **import sound** or **import mypkg**, where are those modules/packages located on your computer?
- all importable packages must be located in one of the folders listed in **sys.path**
- **sys.path** is initialized with
 - current folder
 - installation-dependent defaults
 - PYTHONPATH environment variable
- you can alter **sys.path** during runtime
